SLIDING MODE CONTROL SYNTHESIS OF UNCERTAIN
TIME-DELAY SYSTEMS

Y. Orlov, W. Perruquetti, and J.P. Richard

ABSTRACT

Sliding mode control synthesis is developed for a class of uncertain time-delay systems with nonlinear disturbances and unknown delay values whose unperturbed dynamics is linear. The synthesis is based on a new delay-dependent stability criterion. The controller constructed proves to be robust against sufficiently small delay variations and external disturbances. An admissible upperbound such that the corresponding closedloop system remains globally asymptotically stable for each delay value less than this upperbound is derived. Performance issues of the controller are illustrated in a simulation study.

Keywords: Sliding mode, time-delay system, robustness.

I. INTRODUCTION

The primary concern of the paper is robust control of uncertain time-delay systems within the framework of sliding mode control methods. The sliding mode control paradigm implies the deliberate introduction of so-called sliding motions (i.e., the motions along a manifold where the control signal undergoes discontinuities) into the control system and it consists of two steps [23]. First, a manifold, such that if confined to this manifold the system has desired dynamic properties, is designed. Second, a discontinuous control law, which drives the system to this manifold in finite time, is synthesized.

The sliding mode control strategy is to construct a feedback that guarantees a Lyapunov function, selected for a nominal system, to remain negative on the trajectories of the perturbed system. The controller, thus constructed, asymptotically stabilizes the system and since the motion along the manifold proves to be uncorrupted by matched disturbances, the closed-loop system is additionally guaranteed to have strong robustness properties against matched disturbances. Due to these advantages and simplicity of implementation, sliding mode controllers have widely been used in various applications [24].

Motivated by technological advances, the interest recently emerged in extending the sliding mode control approach to infinite-dimensional dynamic systems such as distributed parameter systems and time-delay systems. The earlier works [19, 27] on extensions of sliding mode control algorithms to infinite-dimensional systems ran into a major difficulty, caused by the presence of an unbounded infinitesimal operator in the plant equation, and called for further theoretical investigations. Presently, the sliding mode control synthesis in the infinite-dimensional setting is well documented [14,15,17,18]. This synthesis retains robustness features, similar to those possessed by its counterpart in the finite-dimensional case, and being complementary to the $H_{\infty}$-design, it constitutes a more practical approach to infinite-dimensional systems than the ones of high computational complexity outlined in [3,6,8,11].

The existing results [1,7,9,10,20,25] on application of sliding mode control algorithms to time-delay systems, governed by functional differential equations (FDE), have corroborated their utility for this class of systems as well. However, these results, being inherited from the finite-dimensional treatment, contained no arguments supporting the well-posedness of FDE solutions to substantiate the stability analysis. Even the solution concept for discontinuous time-delay systems has not yet been addressed.

Resolving the fundamental issue on the precise meaning of FDE with discontinuous right-hand side constitutes one of the contributions of the present paper. Substantial stability analysis and sliding mode control synthesis of time-delay systems with small time lags and
weak nonlinearities is another contribution of the paper. In this regard, it is worth noticing that allowing the weak nonlinearities, introduced in Section 2 by means of Assumptions A1 and A2, admits unmatched disturbances thereby making a step beyond a standard sliding mode control treatment. Specifically, the critical delay value when the closed-loop system, corresponding to this value, becomes asymptotically unstable is explicitly calculated as a function of linear growth constants of the unmatched disturbances.

The outline of the paper is as follows. Plant description and formal problem statement appear in Section 2. After giving background materials on discontinuous time-delay systems in Section 3, Section 4 presents a new delay/disturbance-dependent stability criterion for a class of time-delay systems with nonlinear uncertainties and unknown delay value whose unperturbed dynamics is linear. Based on this criterion, in Section 5 we synthesize a sliding mode controller which asymptotically stabilizes the system for any value of the delay less than its critical value obtained via solving a convex optimization problem. Simulation results are included in Section 6. Finally, Section 7 presents some conclusions.

1.1 Notation

The notation is fairly standard. The matrix inequality $M > 0$ ($M < 0$) means that $M$ is positive (respectively, negative) definite; $I$ denotes the identity matrix of an appropriate dimension. The vector norm $\|e\|$ stands for the Euclidean norm of a vector $e$ whereas the matrix norm

$$
\|M\| = \sup_{\|e\| = 1} \|Me\|
$$

stands for the induced norm of a matrix $M$; $L^p_\tau[-\tau, 0]$ denotes the Hilbert space of square integrable $(n)$-vector functions defined on the segment $[-\tau, 0]$.

II. PROBLEM STATEMENT

In this paper, we focus on time-delay systems that are representable by means of a nonlinear change of state coordinates and a feedback transformation, in the form

$$
\begin{align*}
\frac{dz_1(t)}{dt} &= \sum_{i=1}^{2}(A_{1i}z_i(t) + B_{1i}z_i(t - \tau)) \\
&\quad + p_1(t, z(t)) + p_2(t, z(t - \tau)), \\
\frac{dz_2(t)}{dt} &= \sum_{i=1}^{2}(A_{2i}z_i(t) + B_{2i}z_i(t - \tau)) \\
&\quad + u + f(t, z), \\
z(t) &= \phi(t) \text{ for } t \in [-\tau, 0].
\end{align*}
$$

Hereinafter, $z(t) = (z_1, z_2)^T$ is the state vector with components $z_1 \in \mathbb{R}^n$, $z_2 \in \mathbb{R}^r$, $A_{ij}, B_{ij}, i, j = 1, 2$ are constant matrices of corresponding dimensions, $u \in \mathbb{R}^r$ is the input vector; $p_1, p_2 \in \mathbb{R}^n$ and $f \in \mathbb{R}^r$ are external disturbances, $\phi$ is the initial piecewise continuous function defined on $[-\tau, 0]$, $z_\theta(t)$ is the function associated with $z$ and defined on $[-\tau, 0]$ by $z_\theta(t) = z(t + \theta)$. Since the delay value $\tau$ is typically unknown a priori, in the sequel we shall also use the notation $z_{\tau, \tau_{\text{max}}}(\theta)$ for the function $z_{\tau, \tau_{\text{max}}}(\theta) = z(t + \theta)$ defined on some larger interval $[-\tau_{\text{max}}, \theta]$ with $\tau_{\text{max}} > \tau$.

Setting

$$
\begin{align*}
A_0 &= \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad B_0 = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}, \\
P_1 &= \begin{pmatrix} p_1 \\ 0 \end{pmatrix}, i = 1, 2, \quad C = \begin{pmatrix} 0 \\ I \end{pmatrix}, \quad F = \begin{pmatrix} 0 \\ f \end{pmatrix}
\end{align*}
$$

system (1) can be simplified to

$$
\begin{align*}
\dot{z}(t) &= A_0z(t) + B_0z(t - \tau) + Cu + P_1(t, z(t)) \\
&\quad + P_2(t, z(t - \tau)) + F(t, z).
\end{align*}
$$

Although our investigation is confined to time-delay systems with delayed states, however, the extension to the case of delayed inputs is straightforward. Indeed, let a system with an input delay be governed by

$$
\begin{align*}
\dot{x}(t) &= Ax(t) + Bx(t - \tau) + Du(t - t), \quad t > 0 \\
x(t) &= \psi_1(t), \quad t \in [-\tau, 0], \\
u(t) &= \psi_2(t), \quad t \in [-\tau, 0]
\end{align*}
$$

where $x \in \mathbb{R}^n$, $A, B$ are constant $n \times n$ matrices, $D$ is a $n \times r$ matrix, $u \in \mathbb{R}^r$ is the input vector, $\psi_1$ and $\psi_2$ are piecewise continuous functions. Then, an additional input integrator transforms the system into the above form

$$
\begin{align*}
\frac{dz_1(t)}{dt} &= Az_1(t) + Bz_1(t - \tau) + Dz_1(t - \tau), \\
\frac{dz_2(t)}{dt} &= \nu
\end{align*}
$$

with the control input $\nu \in \mathbb{R}^r$.

Throughout the paper, the following assumptions are made for technical reasons:

- A1) $p_1(t, z(t))$ and $p_2(t, z(t - \tau))$ are Lipschitz continuous and satisfy the linear growth conditions

$$
\begin{align*}
\|p_1(t, z(t))\| \leq \alpha_1 \|z(t)\|, \quad \|p_2(t, z(t - \tau))\| \leq \alpha_2 \|z(t - \tau)\|
\end{align*}
$$

with some positive constants $\alpha_1, \alpha_2$.

- A2) $f$ is Lipschitz continuous and it is bounded by a continuous functional
Ψ(t, z, τmax) known a priori.

A3) \((A_{11} + B_{11}, A_{12} + B_{12})\) is controllable.

Assumptions A1 and A2, coupled together, guarantee the unforced FDE (1) with \(u = 0\) to have a unique solution for all \(t \geq 0\) [13]. Apart from this, Assumption A2 allows us to reject the uncertain disturbance \(f\) by a bounded-gain sliding mode feedback. Assumption A3 implies the controllability of the delay/disturbance-free system (1) subject \(p_1 = p_2 = 0, \tau = 0, f = 0\) (see [23, p.101] for details).

Thus, the above assumptions ensure that a delay-free system (1) with \(\tau = 0\) turns out to be stabilizable under sufficiently small external disturbances \(p_1, p_2, f\). Due to conservatism, time-delay systems of the form (1) remain stabilizable for all \(\tau \leq \tau_{\text{max}}\) with some positive, sufficiently small \(\tau_{\text{max}}\). The goal of the present investigation is to construct a stabilizing sliding mode controller of (1) that makes the value of \(\tau_{\text{max}}\) as large as possible.

III. BACKGROUND MATERIALS ON DISCONTINUOUS TIME-DELAY SYSTEMS

Since the closed-loop system, driven by a sliding mode controller, is governed by a FDE with discontinuous right-hand side, the precise meaning of such an equation should first be defined. For this purpose, let us represent the time-delay system (3) as a dynamic system

\[
\frac{d\zeta}{dt} = A\zeta + Cu + P_1(t, \mu(t)) + P_2(t, v(-\tau)) + \mathcal{F}(t, v)
\]

evolving in the Hilbert space \(M_2^{acr} = \mathbb{R}^{acr} \times L_2^{acr}[-\tau, 0]\) whose state \(\zeta = (\mu(t), v(\cdot))'\) at a time moment \(t\) consists of the components \(\mu(t) = z(t) \in \mathbb{R}^{acr}\) and \(v(\theta) = z(\theta) \in L_2^{acr}[-\tau, 0]\), and the linear operators

\[
A : \mathcal{D}(A) \subset M_2^{acr} \rightarrow M_2^{acr}, \mathcal{C} : \mathbb{R} \rightarrow M_2^{acr}
\]

and nonlinear operators

\[
P_i : \mathbb{R}^{acr} \rightarrow M_2^{acr}, i = 1, 2, \mathcal{F} : M_1 \rightarrow M_2^{acr}
\]

are given by

\[
A = \begin{pmatrix} A_0 & B_0 \end{pmatrix}
\]

\[
C = \begin{pmatrix} C \mu & 0 \end{pmatrix}
\]

\[
P_1 = \begin{pmatrix} P_1(t, \mu(t)) \end{pmatrix}
\]

\[
\mathcal{F} = \begin{pmatrix} \mathcal{F} \end{pmatrix}
\]

Apparently, \(C\) is a bounded operator on \(\mathbb{R}^r\) whereas the nonlinear operators \(P_i, i = 1, 2\) and \(\mathcal{F}\) are Lipschitz continuous on their domains due to Assumptions A1 and A2. In turn, it is well-known [6], that the infinitesimal operator \(A\) generates a (strongly continuous) \(C_0\)-semigroup on \(M_2^{acr}\) and its domain

\[
\mathcal{D}(A) = \{\zeta = (\mu, v)' \in M_2^{acr} : \frac{dv}{d\theta} \in L_2^{acr}[-\tau, 0]\}
\]

and \(v(0) = \mu\) is dense in \(M_2^{acr}\).

Thus, solutions of the Hilbert space-valued dynamic system (6) with discontinuous right-hand side can rigorously be defined in the sense of [18]. For convenience of the reader, we recall the basic idea of that definition.

Let the control input \(u(\zeta)\) undergo discontinuities on some linear manifold \(\mathcal{G}\zeta = 0\) in the state space and let \(u(\zeta)\) be continuously differentiable beyond this manifold. Then trajectories of (6) are well-defined in the conventional sense whenever they are beyond the discontinuity manifold whereas in a vicinity of this manifold the original system is replaced by a related system, whose solutions also exist in the conventional sense. A motion along the discontinuity manifold, if any, is then obtained by making the characteristics of the new system approach those of the original one. Such a motion is further referred to as a sliding mode that has become standard in the literature.

It is worth noting that given an initial condition \(\zeta_0 = (\phi(0), \phi(\cdot)) \in M_2^{acr}, \) the Cauchy problem, thus stated for system (6) with the assumptions above, proves to have a unique solution whenever the operator \(\mathcal{G}\mathcal{C}\) is continuously invertible. Just in case, the sliding motion of the system on the discontinuity manifold is governed by the so-called sliding mode equation derived through the equivalent control method.

The validity of the equivalent control method in infinite-dimensional setting has been justified in [19] for parabolic systems and in [17,18] for more general systems, including hyperbolic and, particularly, time delay systems. According to this method, the sliding mode equation is obtained by substituting the solution

\[
u_{\text{sg}} = -[\mathcal{G}\mathcal{C}]^{-1}\mathcal{G}[A\zeta - P_1(t, \mu(t)) + P_2(t, v(-\tau)) + \mathcal{F}(t, v)]
\]

of the equation \(\mathcal{G}\zeta = 0\) into (6) for \(u(\zeta)\).

The sliding mode equation plays an important role in the subsequent stability analysis of the discontinuous time delay system in question. Since this equation contains no discontinuities in the right-hand side, its stability is established via standard techniques.

IV. DELAY/DISTURBANCE-DEPENDENT STABILITY CRITERION

For later use, we derive delay/disturbance-dependent stability conditions for the time-delay system
\[
\frac{dx(t)}{dt} = Ax(t) + Bx(t - \tau) + p_1(t, x(t)) + p_2(t, x(t - \tau))
\]
\[x \in \mathbb{R}^n, x(t) = \zeta(t) \text{ for } t \in [-\tau, 0] \tag{8}\]

with a piece-wise continuous initial function \(\zeta(t)\), some constant matrices \(A, B, \) and the same nonlinearities as before. Our objective is to find an upperbound \(\tau_{\text{max}}\) of admissible delay values \(\tau\) such that the above system, while being asymptotically stable with \(\tau = 0\), is so for all delays \(0 \leq \tau < \tau_{\text{max}}\). This upperbound \(\tau_{\text{max}} = \tau_{\text{max}}(\alpha_1, \alpha_2)\) depends on the linear growth constants \(\alpha_1, \alpha_2\) of the disturbances \(p_1, p_2\) and relates to a positive solution of the following optimization problem

\[
\tau_{\text{max}}(\alpha_1, \alpha_2) = \sup \tau \text{ subject to the constraints }
\]

\[
\begin{pmatrix}
H(\tau) & P & P A & P B & P A B & P B A 2
\end{pmatrix} < 0
\]

(9)

over all positive constants \(\gamma_i, i = 1, 2, 3, 4\) and symmetric positive definite matrices \(P, R_1, R_2 \in \mathbb{R}^{n \times n}\), and \(H(\tau) = (E^T P + P E) + (\gamma_1 \alpha_1^2 + \gamma_2 \alpha_2^2) J + \gamma_3 \alpha_1^2 + \gamma_4 \alpha_2^2 J + \pi I\). With \(E = A + B\).

**Theorem 1.** Let the matrix \(E = A + B\) be Hurwitz. For \(\alpha_1, \alpha_2 > 0\) sufficiently small, the above optimization problem has a positive solution \(\tau_{\text{max}}(\alpha_1, \alpha_2)\) and system (8) is globally asymptotically stable for each delay value \(\tau \in [0, \tau_{\text{max}}(\alpha_1, \alpha_2)]\).

**Proof.** Consider the following Lyapunov-Krasovskii functional

\[
V(z(t)) = V_1(z(t)) + V_2(z(t)) + V_3(z(t))
\]

\[
V_1(z(t)) = z^T(t)P_2(t)
\]

\[
V_2(z(t)) = \int_{-\tau}^{0} \int_{-\tau}^{0} z^T(w)(R_1 + \gamma_3 \alpha_1^2 I_4)z(w)dwds + \int_{-\tau}^{0} z^T(w)(R_2 + \gamma_4 \alpha_2^2 I_4)z(w)dwds + \frac{\int_{-\tau}^{0} z^T(w)(R_2 + \gamma_4 \alpha_2^2 I_4)z(w)dwds}{\int_{-\tau}^{0} z^T(w)z(w)dwds}
\]

\[
V_3(z(t)) = \gamma_3 \alpha_1^2 \int_{-\tau}^{0} z^T(w)z(w)dwds
\]

with \(P, R_1, R_2\) symmetric positive definite matrices, and positive \(\gamma_i, i = 1, 2, 3, 4\). The functional \(V(z(t))\) is positive definite and radially unbounded. Using \(z(t - \tau) = \int_{-\tau}^{0} \hat{z}(0)d\theta + z(t)\), we can rewrite the system in the form

\[
\frac{dz(t)}{dt} = (A + B)z(t)
\]

\[
-B \left[ \int_{-\tau}^{0} [Az(w) + Bz(w - \tau) + p_1(w, z(w)) + p_2(w, z(w - \tau))]dw + p_1(t, z(t)) + p_2(t, z(t - \tau)) \right].
\]

Let us now calculate the derivative of \(V(z(t))\) along the trajectories of the system (8):

\[
\dot{V}_1 = z^T(E^TP + PE)z + 2z^TP_1z + 2z^TP_2z
\]

\[
-2z^TPB_{1,t}^n z(w)dw
\]

\[
-2z^TPB_{2,t}^n z(w - \tau)dw
\]

\[
-2z^TPB_{1,t}^n z(w, z(w))dw
\]

\[
-2z^TPB_{2,t}^n z(w, z(w - \tau))dw
\]

(11)

Due to the well-known inequality \(2u^Tv \leq \alpha u^TRu + \alpha^T u^TRu\), valid for any vectors \(u, v \in \mathbb{R}^n\), symmetric positive definite matrix \(R \in \mathbb{R}^{n \times n}\) and positive constant \(\alpha\), the following six inequalities are in force:

\[
2z^TP_1 \leq z^T(\gamma_1 \alpha_1^2 I + \gamma_3 \alpha_1^2 I)z,
\]

\[
2z^TP_2 \leq z^T(\gamma_2 \alpha_2^2 I + \gamma_4 \alpha_2^2 I)z,
\]

\[
-2z^TPB_{1,t} \leq \tau z^T Z_1 z + \int_{-\tau}^{0} z^T(w) R_1 z(w)dw
\]

\[
-2z^TPB_{2,t} \leq \tau z^T Z_2 z + \int_{-\tau}^{0} z^T(w) R_2 z(w)dw
\]

\[
+ \int_{-\tau}^{0} z^T(w) R_3 z(w)dw
\]

\[
-2z^TPB_{1,t} \leq \tau z^T Z_3 z + \int_{-\tau}^{0} z^T(w) R_4 z(w)dw
\]

\[
+ \int_{-\tau}^{0} z^T(w) R_5 z(w)dw
\]

\[
-2z^TPB_{2,t} \leq \tau z^T Z_4 z + \int_{-\tau}^{0} z^T(w) R_6 z(w)dw
\]

\[
+ \int_{-\tau}^{0} z^T(w) R_7 z(w)dw
\]

with \(I\) identity matrix,

\[
Z_1 = PBAR^{-1}A^TB^T P,
\]

\[
Z_2 = PB_2^2 R_1^2 B_2^T P,
\]

\[
Z_3 = PBB^T P,
\]

\[
\gamma_i > 0, i = 1, 2, 3, 4.
\]
Now it follows from (11) that the inequality

\[
\dot{V}(z_t) \leq z^T M(\tau) z
\]

holds for

\[
M(\tau) = (E^T P + PE) + (\gamma_1^{-1} + \gamma_2^{-1}) P^2 + \tau PBAR^{-1} + \tau R_1 + B^T P + \tau PBB^T + \tau \gamma_1^{-1} PBB^T P.
\]

The matrix \( E \) is Hurwitz and hence \( M(0) = (E^T P + PE) + (\gamma_1^{-1} + \gamma_2^{-1}) P^2 \) is negative definite if \( P \) is a symmetric positive definite solution of the Lyapunov equation \( E^T P + PE = -I \) and positive constants \( \gamma_1, \gamma_2 \) are sufficiently small. By continuity \( M(\tau) \) remains negative definite for sufficiently small positive \( \tau \). Since by Schur’s lemma \( 2 \), \( M(\tau) \) is positive definite for all \( \tau \in [0, \tau_{\text{max}}(\alpha_1, \alpha_2)] \) and system (8) is therefore globally asymptotically stable for all delays \( 0 \leq \tau < \tau_{\text{max}}(\alpha_1, \alpha_2) \). Theorem 1 is proven.

**Remark 2.** The inequality (9) is a linear matrix inequality in \( P, R_1, R_2, \gamma_1, \gamma_2, \gamma_3, \gamma_4 \) and can efficiently be solved by convex optimization algorithms (see [2]).

**Example 3.** (Comparison with other criteria) Let system (8) be specified by

\[
A = \begin{pmatrix} -2 & 0 \\ 0 & -1 \end{pmatrix}, \quad B = \begin{pmatrix} -1 & 0 \\ 1 & -1 \end{pmatrix}
\]

and let \( p_1 \) and \( p_2 \) be such that \( \|p_1\| \leq 0.2 \|z_t\| \) and \( \|p_2\| \leq 0.2 \|z_t\| \). Using Theorem 1, we find \( \tau_{\text{max}}(0.2, 0.2) = 0.623 \) whereas the largest upperbound of time-delay available in the literature (see \([16,21,22]\)) is \( \tau_{\text{max}} = 0.4428 \). It should also be noted that neither the disturbance-free criteria from \([9,10]\) nor the delay-independent criterion from \([26]\) is capable of providing any conclusion. Thus, the example shows that the proposed criterion makes a step beyond the existing results.

**V. SLIDING MODE STATE FEEDBACK CONTROLLER**

The following state feedback control law

\[
u = -[\Omega_\psi(t, z_t, \tau_{\text{max}}, \alpha_1, \alpha_2)] + [\Psi(t, z_t, \tau_{\text{max}})] + g[H(z_t)]^T s(z(t)) / \|s(z(t))\|.
\]

where

\[
g > 0, \quad \varepsilon \in [0, 1)
\]

is proposed to drive the uncertain time-delay system (1) to a linear manifold \( s(z) = 0 \) with

\[
s(z) = z_2 + Kz_1
\]

in finite time thereby globally asymptotically stabilizing the system for each \( \tau \in [0, \tau_{\text{max}}] \). Hereinafter, \( \Psi(t, z_t, \tau_{\text{max}}) \) is the same upperbound of the norm of the time-delay of the external disturbances \( f(t, z_t) \) as it is in Assumption A2, \( z_t, \tau_{\text{max}}(\theta) \) stands for the function \( z(t - \theta) \) with \( \theta \in [-\tau_{\text{max}}, 0] \) and \( \tau_{\text{max}} > \tau \), the linear functional

\[
\Omega(t, z_t) = \sum_{i=1}^{2} [A_{i} z_i(t) + B_{i} z_i(t - \tau) + K [A_{i} z_i(t) + B_{i} z_i(t - \tau)]]
\]

is viewed on the trajectories of the controlled system (1), and

\[
\Omega_\psi(t, z_t, \tau_{\text{max}}, \alpha_1, \alpha_2) = \sup_{\theta \in [-\tau_{\text{max}}, 0]} \|\Omega(t, z_t(\theta))\|
\]

is its upperbound\(^1\) on a time interval \( \theta \in [-\tau_{\text{max}}, 0] \) whereas \( \tau_{\text{max}} = \tau_{\text{max}}(\alpha_1, \alpha_2) \) and \( K \in \mathbb{R}^{n_0} \) are subject to the optimization

\[
\tau_{\text{max}}(\alpha_1, \alpha_2) = \sup_{\tau} \tau
\]

under the constraints

\[
\begin{cases}
J(\tau) = S \gamma_1 L(\tau) + \tau S \gamma_5 L(\tau) - \gamma_5 L(\tau) \tau S \geq 0, \\
S = \begin{pmatrix} -\gamma_1^{-1} \alpha_1^2 I_n & 0 \\ 0 & -\gamma_1^{-1} \alpha_2^2 I_n \end{pmatrix}, \\
\tau S = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \\
\gamma_5 L(\tau) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \\
-\gamma_5 \alpha_1^2 I_n \leq 0, \\
0 \leq -\tau_2 Q_1, \\
0 \leq -\tau_2 Q_2 \leq 0, \\
(A_{i1} - A_{i2} K) S < \gamma^2 S, \\
(B_{i1} - B_{i2} K) S < \gamma_1 S \\
S > 0, Q_1 > 0, Q_2 > 0, \gamma_1 > 0, i = 1, \ldots, 6
\end{cases}
\]

\(^1\)Due to Assumption A1, such an upperbound can be chosen to only depend upon the linear growth constants \( \alpha_1, \alpha_2 \) of the external disturbances \( p_1 \) and \( p_2 \) regardless of a concrete realization of these disturbances.
with symmetric positive definite matrices $S$, $Q_1$, $Q_2 \in \mathbb{R}^{(n-m)\times(n-m)}$,
\[
J(\tau) = [(A_1 + B_1) - (A_2 + B_2)K]S \\
+ S[(A_1 + B_1) - (A_2 + B_2)K]^T \\
+ [\gamma_1^+ + \gamma_2^+ + \tau(\gamma_1^- + \gamma_4^-)\gamma_6^+]J + \tau(Q_1 + Q_2),
\]
and $L(\tau) = \tau(\tau_1 - B_1\tau)S$.

It is of interest to note that if system (1) is only affected by external disturbances $f(t, z)$, vanishing in the origin, then an upperbound $\Psi(t,z_{t_{\tau_{\text{max}}}})$, such that $\Psi(t,0) = 0$ for all $t$, becomes available so that the corresponding controller (13) with a positive parameter $\varepsilon$ is continuous in the origin with no undesirable effects of switching in the steady state.

It should be pointed out that the control law (13) appears to be applicable even if the system delay is unknown a priori.

We are now in a position to state the main result of this section.

**Theorem 4.** Let Assumptions A1-A3 be satisfied. Then for $\alpha$, $\alpha_1$ sufficiently small the optimization problem (15) has a positive solution $\tau_{\text{max}}(\alpha_1, \alpha_2)$ and the closed-loop system (1), (13) is globally asymptotically stable for each delay value $\tau \in [0, \tau_{\text{max}}(\alpha_1, \alpha_2))$.

**Proof.** We break up the proof in 3 simple steps. Firstly, we prove that the discontinuity manifold $s(z) = 0$ is reached in finite time, secondly, we derive the state equations along the manifold $s(z) = 0$, and thirdly, we prove the asymptotic stability of the system motion on this manifold, thereby completing the proof of Theorem 4.

1) **Attractiveness of the manifold.** Taking into account that the time derivative of $s(z(t))$ along the solutions of (1) is given by
\[
\dot{s}(z(t)) = \Omega(t, z) + f(t, z),
\]
differentiating the Lyapunov-Krasovskii functional
\[
V(t) = \frac{s^T(z(t))s(z(t))}{2},
\]
on the trajectories of the closed-loop system under Assumptions A1-A3 yields
\[
\dot{V}(t) = s^T(z(t))\dot{s}(z(t)) = s^T(z(t))\{\Omega(t, z) + f(t, z) \}
- [\Omega_n(t, z_{t_{\tau_{\text{max}}}}, \alpha_1, \alpha_2) + \Psi(t, z_{t_{\tau_{\text{max}}}}) + g_1(f(t, z))](17)
\]
\[
< - g_2 \|s(z(t))\|_{\varepsilon_1} \leq -2gV(t)^{\varepsilon_1}.
\]
Since an arbitrary solution of the latter inequality is well-known to vanish after a finite time moment, the finite-time convergence of the trajectories of the closed-loop system to the discontinuity manifold $s(z) = 0$ is concluded. In order to reproduce this conclusion, one should note that for all $t \geq 0$ arbitrary solution $V(t)$ to the latter inequality is dominated $V(t) \leq V_0(t)$ by the solution to the differential equation $\dot{V}_0(t) = -2gV_0(t)^{\varepsilon_1}$, initialized with the same initial condition $V_0(0) = V(0)$. Since $V(0) = 0$ for all $t \geq 0$, $V(t)$ vanishes after the finite time moment $T = \frac{2}{g(1-\varepsilon)}V(0)^{\varepsilon_1}$.

2) **Sliding mode equation.** In order to describe the system motion on the discontinuity manifold $s(z) = 0$ one should follow the extension [17] of the equivalent control method [23] to infinite-dimensional systems driven in a Hilbert space. According to this method, the continuous solution $u_{eq} = -[\Omega(t, z) + f(t, z)]$ of the equation $\dot{s} = 0$ is substituted into (1) for $u$. Thus, on the discontinuity manifold, the system is governed by the differential equation
\[
\frac{dz}{dt} = (A_{11} - A_{12}K)z_1(t) + (B_{11} - B_{12}K)z_2(t) \\
+ p_1(t, z_1(t)) + p_2(t, z_2(t)),
\]
where $A_{11} - A_{12}K$ is Hurwitz by a proper choice of the matrix $K$.

Applying Theorem 1 to the sliding mode equation (18), we obtain that the optimization problem (15) has a positive solution $\tau_{\text{max}}(\alpha_1, \alpha_2)$. Moreover, as in proving Theorem 1, (18) is asymptotically stable if
\[
(\Sigma E^T + E\Sigma + (\gamma_1^- + \gamma_4^-)I_{n-r})S
+ (\gamma_1^+ + \gamma_4^+)\gamma_6^+\gamma_6^-S^2
\]
\[
+ \tau(\Sigma R_{11} + \Sigma R_{12} + \Sigma R_{21} + \Sigma R_{22})S
\]
\[
+ (\tau\gamma_6^+ + \tau\gamma_6^-)BB^T < 0
\]
where $A = A_{11} - A_{12}K$ and $B = B_{11} - B_{12}K$.

In turn, under constraints
\[
Q_1 = \Sigma R_{11}, Q_2 = \Sigma R_{12}, A_{11} - A_{12}KS < \gamma_5^+ S, \\
B_{11} - B_{12}KS < \gamma_6^+ S
\]
(20) with some positive $\gamma_5^+, \gamma_6^+$, inequality (19) results from
\[
(\Sigma E^T + E\Sigma + (\gamma_1^- + \gamma_4^-)I_{n-r})L_{n-r}
+ (Q_1 + Q_2) + (\gamma_1^+ + \gamma_4^+)\gamma_3^+\gamma_3^-S^2
\]
Since (21) is equivalent to (15) by Schur’s Lemma [2], the global asymptotic stability of the sliding mode equation (18) is then concluded for each delay value \( \tau \in [0, \tau_{\text{max}}(\alpha_1, \alpha_2)] \). Theorem 4 is completely proven.

**Remark 5.** While \( \gamma_i > 0, i = 1, \ldots, 6 \) being fixed, (15) is a generalized eigenvalue problem which can efficiently be solved by convex optimization. A suboptimal upper-bound \( \tau_{\text{max}}(\alpha_1, \alpha_2) \) is thus found by relaxation type algorithms.

**VI. EXAMPLE**

Consider system (3) with

\[
A_0 = \begin{pmatrix} 2 & 0 & 1 \\ 1.4 & 0.25 & 0.8 \\ -1 & 0 & 1 \end{pmatrix}, \quad B_0 = \begin{pmatrix} -1 & 0.25 & 0.2 \\ -0.2 & 4 & 5 \end{pmatrix},
\]

\[
C = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad F = \begin{pmatrix} 0 \\ 0 \\ \sin(z(t) - \tau) \end{pmatrix}, \quad P_1 = P_2 = 0
\]  
(22)

and the initial condition

\[
(23)
\]

Let the sliding surface (14) be specified with \( K = (1.317, 3.979) \). Then by using semidefinite programming, system (3), (22), driven by the sliding mode controller (13) subject to \( \epsilon = 0, \Psi(t, z_{\tau_{\text{max}}}) = \max_{\omega \in [0, \tau_{\text{max}}]} \|z(t)\|, g = 1.1 \), is globally asymptotically stable for each delay value \( \tau \in [0, \tau_{\text{max}}] \) where \( \tau_{\text{max}} = 0.63 \). The simulation results depicted in Fig. 1 are obtained with a 5th order integration scheme of step \( 10^{-3} \).

By setting \( \epsilon = \frac{1}{2} \), the control input becomes continuous in the origin and the chattering phenomenon is thus drastically reduced. As shown in Fig. 2, the amplitudes of the input oscillations, coming in this simulation run, are reduced from 2 to 0.02 without apparent changes in the convergence rate.

**Remark 6.** Comparison with previous results: The sliding mode controllers proposed in [4,20] cannot stabilize system (22) since the pair \((A_0, C)\) is not controllable in this case. With our approach, \((A_0 + B_0, C)\)-controllability relaxes this requirement. The standard linear state feedback, developed in [16,26], can only attenuate vanishing disturbances. Controllers from [5], which are based on linear models over rings and reject nonvanishing distur-

Fig. 1. Response of the closed-loop system (3), (13), (22) with \( \tau = 0.63 \) and \( \epsilon = 0 \).
Discontinuous time-delay control systems are under study. The system behavior on the manifold where the controller undergoes discontinuities is shown to be governed by the equation obtained through the equivalent control method extended to Hilbert space-valued dynamic systems. Based on this observation, sliding mode control synthesis, robust against sufficiently small delay variations and external disturbances, is developed for a class of uncertain nonlinear time-delay systems. The synthesis consists of two steps. First, a manifold, such that if confined to this manifold the time delay system has desired dynamic properties, is designed. Second, a discontinuous control law, which drives the system to this manifold in finite time, is synthesized. An admissible upperbound such that the corresponding closed-loop system remains globally asymptotically stable for all delay values less than this upperbound is derived. Theoretical results are supported by a numerical example.
